

## Formulas & Methodology

### 1. Sum, Count, and Average

- The SUM function was used to calculate the total price of all products by adding the values in the price column.
- The COUNTA function was used to determine the number of products in the dataset.
- The AVERAGE function was then applied to the price column to calculate the mean product price.

### 2. Minimum and Maximum

- The MIN and MAX functions were applied to the price column to identify the lowest and highest priced products, respectively.

### 3. IF Function

- An IF function was used to create the Price Range column, classifying each product as "High Price" if its price is greater than or equal to \$500, and "Standard Price" otherwise. The \$500 threshold was entered as a separate labelled.

### 4. SUMIF and COUNTIF

- The SUMIF function was used to calculate the total price of products within the "Electronics" category by summing only the price values corresponding to that category. The COUNTIF function was used to determine the number of products priced below \$100 by applying a "less than 100" condition to the price column.

### 5. Text Functions LEFT, RIGHT, and MID

The Product ID field follows a consistent structure combining a day, month, and country code. Based on this fixed format, the LEFT function was used to extract the day component from the beginning of the text string, the RIGHT function was used to extract the country code from the end of the string, and the MID function was used to extract the month component from the middle of the string.
